Chapter 1

Bar and Cobar Construction

A strongly homotopy associative algebra, or A_∞ -algebra, over a field is a graded vector space together with homogenous linear maps $m_n : A^{\otimes n} \rightarrow A$ of degree $n - 2$ satisfying some homotopical relations. This will be made precise later. We may regard m_2 to be a multiplication of A , it is however not a priori associative. The associator of m_2 is taken to be the homotopical relation of m_3 . Thus, we know that the homotopy of A is an associative algebra. The maps m_n corresponds uniquely to a map $m^c : BA \rightarrow \bar{A}[1]$, which extends to a coderivation $m^c : BA \rightarrow BA$ of the bar construction of A . So we could instead define an A_∞ -algebra to be a coalgebra on the form BA .

In order to understand the bar construction we will first study it on associative algebras. Given a differential graded coassociative coalgebra C and a differential graded associative algebra A , we say that a homogenous linear transformation $\alpha : C \rightarrow A$ is twisting if it satisfies the Maurer-Cartan equation:

$$\partial\alpha + \alpha \star \alpha = 0.$$

Let $Tw(C, A)$ be the set of twisting morphisms, then considering it as a functor $Tw : CoAlg_{\mathbb{K}}^{op} \times Alg_{\mathbb{K}} \rightarrow Ab$ we want to show that it is represented in both arguments. Moreover, these representations give rise to an adjoint pair of functors, called the bar and cobar construction.

$$\begin{array}{ccc} & B & \\ \curvearrowright & & \curvearrowleft \\ Aug^\bullet_{Alg_{\mathbb{K}}} & \top & Conil^\bullet_{CoAlg_{\mathbb{K}}} \\ \curvearrowleft & & \curvearrowright \\ & \Omega & \end{array}$$

1.1 Algebras

This section is a review of associative algebras. We will define unital associative algebras and possibly non-unital associative algebras, which we will call algebras and non-unital algebras

respectively. The collection of algebras together with homomorphisms between them form the category $Alg_{\mathbb{K}}$ of algebras. Other types of algebras such as augmented and tensor algebras will be defined as well.

Definition 1.1.1 (Algebra). Let \mathbb{K} be a field with unit 1. An algebra A over \mathbb{K} is a vector space with structure morphisms called multiplication and unit,

$$\begin{aligned} (\nabla_A) : A \otimes_{\mathbb{K}} A &\rightarrow A \\ v_A : \mathbb{K} &\rightarrow A, \end{aligned}$$

satisfying the associativity and identity laws.

$$\begin{aligned} \text{(associativity)} \quad (a \nabla_A b) \nabla_A c &= a \nabla_A (b \nabla_A c) \\ \text{(unitality)} \quad v_A(1) \nabla_A a &= a = a \nabla_A v_A(1) \end{aligned}$$

Whenever A does not possess a unit morphism, we will call A a non-unital algebra. Only the associativity law must hold.

Definition 1.1.2 (Algebra homomorphisms). Let A and B be algebras. Then $f : A \rightarrow B$ is an algebra homomorphism if

1. f is \mathbb{K} -linear
2. $f(ab) = f(a)f(b)$
3. $f \circ v_A = v_B$

Whenever A and B are non-unital, we only require 1 and 2 for a homomorphism of non-unital algebras.

Definition 1.1.3 (Category of algebras). • Let $Alg_{\mathbb{K}}$ denote the category of algebras. Its objects consists of every algebra A , and the morphisms are algebra homomorphisms. The sets of morphisms between A and B are denoted as $Alg_{\mathbb{K}}(A, B)$.
• Let $nAlg_{\mathbb{K}}$ denote the category of non-unital algebras. Its objects consists of every non-unital algebra A , and the morphisms are non-unital algebra homomorphisms. The sets of morphisms between A and B are denoted as $nAlg_{\mathbb{K}}(A, B)$.

Observe that for an algebra A , the triple (A, ∇_A, v_A) is a monoid in $mod_{\mathbb{K}}$. Thus, we may say that an algebra is a triple where the following diagrams commute.

$$\begin{array}{ccc} A \otimes_{\mathbb{K}} A \otimes_{\mathbb{K}} A & \xrightarrow{(\nabla_A) \otimes id_{\mathbb{K}}} & A \otimes_{\mathbb{K}} A \\ \downarrow id_{\mathbb{K}} \otimes (\nabla_A) & & \downarrow (\nabla_A) \\ A \otimes_{\mathbb{K}} A & \xrightarrow{(\nabla_A)} & A \end{array} \quad \begin{array}{ccc} A \otimes_{\mathbb{K}} \mathbb{K} & \xrightarrow{id_A \otimes v_A} & A \otimes_{\mathbb{K}} A \xleftarrow{v_A \otimes id_A} \mathbb{K} \otimes_{\mathbb{K}} A \\ & \searrow \simeq & \downarrow (\nabla_A) \swarrow \simeq \\ & & A \end{array}$$

The final method we will use to represent an algebra are electric circuits. An electric circuit is a diagram read from top to bottom, where each column represent a different vector space in a tensor. Morphisms in such diagrams are figures, conjunctions, twistings and etc. E.g. The multiplication operator may be represented as a converging fork, and the unit as a source.

Using these operations we can now reformulate the algebra laws. These are the electric laws for an algebra:

Definition 1.1.4 (Augmented algebras). Let A be an algebra. It is called augmented if there is an algebra homomorphism $\varepsilon : A \rightarrow \mathbb{K}$.

Definition 1.1.5 (Tensor algebra). Let V be a \mathbb{K} -module. We define the tensor algebra $T(V)$ of V as the module

$$T(V) = \mathbb{K} \oplus V \oplus V^{\otimes 2} \oplus V^{\otimes 3} \oplus \dots$$

Given two strings $v^1..v^i$ and $w^1...w^j$ in $T(V)$ we define the multiplication by the concatenation operation.

$$\begin{aligned} \nabla_{T(V)} : T(V) \otimes_{\mathbb{K}} T(V) &\rightarrow T(V) \\ (v^1 \dots v^i) \otimes (w^1 \dots w^j) &\mapsto v^1 \dots v^i w^1 \dots w^j \end{aligned}$$

The unit is given by including \mathbb{K} into $T(V)$.

$$\begin{aligned} v_{T(V)} : \mathbb{K} &\rightarrow T(V) \\ 1 &\mapsto 1 \end{aligned}$$

Observe that the tensor algebra is augmented. The projection from $T(V)$ into \mathbb{K} is an algebra homomorphism, so we may split the tensor algebra into its unit and its augmentation ideal $T(V) \simeq \mathbb{K} \oplus \bar{T}(V)$. We call $\bar{T}(V)$ the reduced tensor algebra.

Proposition 1.1.6 (Tensor algebra is free). *The tensor algebra is the free algebra over the category of \mathbb{K} -modules, i.e. for any \mathbb{K} -module V there is a natural isomorphism $\text{Hom}_{\mathbb{K}}(V, A) \simeq \text{Alg}_{\mathbb{K}}(T(V), A)$.*

The reduced tensor algebra is the free non-unital algebra over the category of \mathbb{K} -modules, i.e. for any \mathbb{K} -module V there is a natural isomorphism $\text{Hom}_{\mathbb{K}}(V, A) \simeq \text{nAlg}_{\mathbb{K}}(T(\bar{V}), A)$.

Proof. This proposition should be evident from the description of an algebra homomorphism from a tensor algebra. If $f : T(V) \rightarrow A$ is an algebra homomorphism, then f must satisfy the following conditions:

- (Unitality) $f(1) = 1$
- (Homomorphism property) Given $v, w \in V$, then $f(vw) = f(v)\nabla_A f(w)$

By induction, we see that f is completely determined by where it sends the elements of V . Thus restriction by the inclusion of V into $T(V)$ induces a bijection. \square

Definition 1.1.7 (Modules). Let A be an algebra. A \mathbb{K} -module M is said to be a left (right) A -module if there exists a structure morphism $\mu_M : A \otimes_{\mathbb{K}} M \rightarrow A$ ($\mu_M : M \otimes_{\mathbb{K}} A \rightarrow A$) called multiplication. We require that μ_M is associative with respect to the multiplication and preserves the unit of A , i.e. the electric laws are satisfied.

Definition 1.1.8 (A -linear homomorphisms). Let M, N be two left A -modules. A morphism $f : M \rightarrow N$ is called A -linear if it is \mathbb{K} -linear and for any a in A , $f(am) = af(m)$.

The category of left A -modules is denoted as Mod_A , where the morphisms $\text{Hom}_A(-, -)$ are A -linear. Likewise, the category of right A -modules is denoted as Mod^A .

Proposition 1.1.9. *Let M be a \mathbb{K} -module. The module $A \otimes_{\mathbb{K}} M$ is a left A -module. Moreover, it is the free left module over \mathbb{K} -modules, i.e. there is an isomorphism $\text{Hom}_{\mathbb{K}}(M, N) \simeq \text{Hom}_A(A \otimes_{\mathbb{K}} M, N)$.*

1.2 Coalgebras

This section aims to dualize the definitions from last section. To this end we will define counital coassociative coalgebras and non-counital coassociative coalgebras, which will be called coalgebras and non-counital coalgebras respectively. The collection of coalgebras together with coalgebra homomorphisms is the category $CoAlg_{\mathbb{K}}$. Due to some ill-behavior, this dualization is only a true dualization under some finiteness conditions for the algebras. Thus we will see that the proper dual concept will be of conilpotent coalgebras. We will see that the cofree coalgebra is conilpotent.

Definition 1.2.1 (Coalgebra). Let \mathbb{K} be a field. A coalgebra C over \mathbb{K} is a \mathbb{K} -module with structure morphisms called comultiplication and counit,

$$\begin{aligned}(\Delta_C) : C &\rightarrow C \otimes_{\mathbb{K}} C \\ \varepsilon_C : C &\rightarrow \mathbb{K},\end{aligned}$$

satisfying the coassociativity and coidentity laws.

$$\begin{aligned}(\text{coassociativity}) \quad &(\Delta_C \otimes id_C) \circ \Delta_C(c) = (id_C \otimes \Delta_C) \circ \Delta_C(c) \\ (\text{counitality}) \quad &(id_C \otimes \varepsilon_C) \circ \Delta_C(c) = c = (\varepsilon_C \otimes id_C) \circ \Delta_C(c)\end{aligned}$$

We define repeated application of comultiplication as $\Delta_C^n = (\Delta_C \otimes id_C \otimes \dots) \circ \Delta_C^{n-1}$. Notice that the choice of where we put comultiplication in the tensor does not matter, as coassociativity require all of the choices to be equal.

We may dualize the electric circuits of an algebra to coalgebras. In this manner our structure morphisms would be upside down relative to the algebra morphisms. Thus comultiplication becomes a diverging fork and counit is a sink.

$$\begin{array}{ccc}(\text{Comultiplication}) & \begin{array}{c} \text{---} \\ | \\ \bigcirc \Delta_C \\ | \\ \text{---} \end{array} = \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \text{---} \end{array} & (\text{Counit}) \quad \begin{array}{c} \text{---} \\ | \\ \bigcirc \varepsilon_C \end{array} = \begin{array}{c} \text{---} \\ \bigcirc \end{array} \end{array}$$

We then obtain the electric laws for a coalgebra by flipping the circuits around.

$$\begin{array}{ccc}(\text{Coassociativity}) & \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \diagup \quad \diagdown \\ \text{---} \end{array} = \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \diagdown \quad \diagup \\ \text{---} \end{array} & \\ (\text{Counitality}) & \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \bigcirc \end{array} = \begin{array}{c} \text{---} \\ | \\ \bigcirc \end{array} = \begin{array}{c} \text{---} \\ \diagdown \quad \diagup \\ \bigcirc \end{array} & \end{array}$$

Definition 1.2.2 (Coalgebra homomorphism). Let C and D be coalgebras. Then $f : C \rightarrow D$ is a coalgebra morphism if

1. f is \mathbb{K} -linear
2. $(f \otimes f) \circ \Delta_C(c) = \Delta_D(f(c))$
3. $\varepsilon_D(f) = \varepsilon_C$

Whenever C and D are non-counital, we only require 1 and 2 for a homomorphism of non-counital coalgebras.

Definition 1.2.3 (Category of Coalgebras). • Let $CoAlg_{\mathbb{K}}$ denote the category of coalgebras. Its objects consists of every coalgebra C , and the morphisms are coalgebra homomorphisms. The sets of morphisms between C and D are denoted as $CoAlg_{\mathbb{K}}(C, D)$.
• Let $nCoAlg_{\mathbb{K}}$ denote the category of non-unital algebras. Its objects consists of every non-unital algebra C , and the morphisms are non-unital algebra homomorphisms. The sets of morphisms between C and D are denoted as $nCoAlg_{\mathbb{K}}(C, D)$.

Example 1.2.4 (The coalgebra \mathbb{K}). The field \mathbb{K} can be given a coalgebra structure over itself. Since $\{1\}$ is a basis for \mathbb{K} we define the structure morphisms as

$$\begin{aligned}\Delta_{\mathbb{K}}(1) &= 1 \otimes 1 \\ \varepsilon(1) &= 1.\end{aligned}$$

One may check that these morphisms are indeed coassociative and counital. Thus we may regard our field as either an algebra or coalgebra over itself.

Definition 1.2.5 (Coaugmented coalgebras). Let C be a coalgebra. C is coaugmented if there is a coalgebra homomorphism $v : \mathbb{K} \rightarrow C$.

If C is a coaugmented coalgebra, then it splits as $C \simeq \mathbb{K} \oplus Cokv$. The splitting is given by counitality of v , as $\varepsilon_C(v) = id_{\mathbb{K}}$. We call the cokernel $Cokv = \bar{C}$ for the coaugmentation quotient or reduced coalgebra, and its reduced coproduct may be explicitly given as

$$\bar{\Delta}_C(c) = \Delta_C(c) - 1 \otimes c - c \otimes 1.$$

Definition 1.2.6 (Tensor Coalgebras). Let V be a \mathbb{K} -module. We define the tensor coalgebra $T^c(V)$ of V as the module

$$T^c(V) = \mathbb{K} \oplus V \oplus V^{\otimes 2} \oplus V^{\otimes 3} \oplus \dots$$

Given a string $v^1 \dots v^i$ in $T(V)$ we define the comultiplication by the deconcatenation operation.

$$\begin{aligned}\Delta_{T^c(V)} : T^c(V) &\rightarrow T^c(V) \otimes_{\mathbb{K}} T^c(V) \\ v^1 \dots v^i &\mapsto 1 \otimes (v^1 \dots v^i) + \left(\sum_{j=1}^{n-1} (v^1 \dots v^j) \otimes (v^{j+1} \dots v^i) \right) + (v^1 \dots v^i) \otimes 1\end{aligned}$$

The counit is given by projecting $T^c(V)$ onto \mathbb{K} .

$$\begin{aligned}\varepsilon_{T^c(V)} : T^c(V) &\rightarrow \mathbb{K} \\ 1 &\mapsto 1 \\ v^1 \dots v^i &\mapsto 0\end{aligned}$$

Notice that the tensor coalgebra is coaugmented. Its coaugmentation is given by the inclusion of \mathbb{K} into $T^c(V)$. We may split $T^c(V) \simeq \mathbb{K} \oplus \bar{T}^c(V)$, where $\bar{T}^c(V)$ is the reduced tensor coalgebra.

In order to get cofreeness for the tensor coalgebra we need some finiteness conditions. This is one of the properties which is ill-behaved when we are dualizing the tensor algebra. The extra assumption which we will need is to assume that the coalgebras are conilpotent. Let $C \simeq \mathbb{K} \oplus \bar{C}$ be a coaugmented coalgebra, we define the coradical filtration of C as a filtration $Fr_0 C \subseteq Fr_1 C \subseteq \dots \subseteq Fr_r C \subseteq \dots$ by the submodules:

$$\begin{aligned}Fr_0 C &= \mathbb{K} \\ Fr_r C &= \mathbb{K} \oplus \{c \in \bar{C} \mid \forall n \geq r \bar{\Delta}_C(c) = 0\}.\end{aligned}$$

Definition 1.2.7 (Conilpotent coalgebras). Let C be a coaugmented coalgebra. We say that C is conilpotent if its coradical filtration is exhaustive, i.e. $\varinjlim_r Fr_r C \simeq C$. The subcategory of conilpotent coalgebras will be denoted as $ConilCoAlg_{\mathbb{K}}$ or $^{Conil}_{CoAlg_{\mathbb{K}}}$.

Proposition 1.2.8 (Conilpotent tensor coalgebra). Let V be a \mathbb{K} -module. The tensor coalgebra $T^c(V)$ is conilpotent.

Proof. Let $v \in V$, then $\Delta_{T^c(V)}(v) = 1 \otimes v + v \otimes 1$ and $\bar{\Delta}_{T^c(V)}(v) = 0$. We then observe the following:

$$\begin{aligned}Fr_0 T^c(V) &= \mathbb{K} \\ Fr_1 T^c(V) &= \mathbb{K} \oplus V \\ Fr_r T^c(V) &= \bigoplus_{i \leq r} V^{\otimes i}\end{aligned}$$

This shows that the coradical filtration is exhaustive. □

Proposition 1.2.9 (Cofree tensor coalgebra). The tensor coalgebra is the cofree conilpotent coalgebra over the category of \mathbb{K} -modules, i.e. for any \mathbb{K} -module V and any conilpotent coalgebra C there is a natural isomorphism $Hom_{\mathbb{K}}(\bar{C}, V) \simeq {}^{Conil}_{CoAlg_{\mathbb{K}}}(C, T^c(V))$.

Proof. This proposition should be evident from the description of a coalgebra homomorphism into the a tensor coalgebra. If $g : C \rightarrow T^c(V)$ is a coalgebra homomorphism, then g must satisfy the following conditions:

1. (Coaugmentation) $g(1) = 1$

2. (Counitality) Given $c \in \bar{C}$ then $\varepsilon_{T^c(V)} \circ g(c) = 0$
3. (Homomorphism property) Given $c \in \bar{C}$ then $\Delta_{T^c(V)}(g(c)) = (g \otimes g) \circ \Delta_C(c)$

We will construct the maps for the isomorphism explicitly. If $g : C \rightarrow T^c(V)$ is a coalgebra homomorphism, then composing with projection gives a map $\pi \circ g : C \rightarrow V$. Note that $\pi \circ g(1) = 0$, so this is essentially a map $\pi \circ g : \bar{C} \rightarrow V$. For the other direction, let $\bar{g} : \bar{C} \rightarrow V$. We will then define g as

$$g = id_{\mathbb{K}} \oplus \sum_{i=1}^{\infty} (\otimes^i \bar{g}) \bar{\Delta}_C^{i-1}.$$

Observe that g is well defined, since convergence of the sum follows from conilpotency of C . One may then check that g is a coalgebra homomorphism, which yields the result. \square

Definition 1.2.10 (Comodules). Let C be a coalgebra. A \mathbb{K} -module M is said to be a left (right) C -comodule if there exist a structure morphism $\omega_M : M \rightarrow C \otimes_{\mathbb{K}} M$ ($\omega_M : M \rightarrow M \otimes_{\mathbb{K}} C$) called comultiplication. We require that ω_M is coassociative with respect to the comultiplication of C and preserves the counit of C , i.e. the electric laws are satisfied.

(Coassociativity)

(Counitality)

Definition 1.2.11 (C -colinear homomorphism). Let M, N be two left C -comodules. A morphism $g : M \rightarrow N$ is called C -colinear if it is \mathbb{K} -linear and for any m in M , $\omega_N(g(m)) = (id_C \otimes g)\omega_M(m)$.

The category of left C -comodules is denoted as $CoMod_C$, where the morphisms $CoHom_C(-, -)$ are C -colinear. Likewise, the category of right C -comodules is denoted as $CoMod^C$.

Proposition 1.2.12. Let M be a \mathbb{K} -module. The module $C \otimes_{\mathbb{K}} M$ is a left C -comodule. Moreover, it is the cofree left comodule over \mathbb{K} -modules, i.e. there is an isomorphism $Hom_{\mathbb{K}}(N, M) \simeq CoHom_C(N, C \otimes_{\mathbb{K}} M)$.

1.3 Derivations and DG-Algebras

In this section we will look at differential graded objects and convolution products. We will define derivations and coderivations to obtain differential graded algebras and coalgebras. Moreover

we will see that the set of homogenous homomorphisms between differential graded objects is itself differential graded. Moreover, whenever we look at morphisms between dg coalgebras and dg algebras, we can give this object the convolution operator, making the set a dg algebra.

Definition 1.3.1 (Derivations and Coderivations). Let M be an A -bimodule. A \mathbb{K} -linear morphism $d : A \rightarrow M$ is called a derivation if $d(ab) = d(a)b + ad(b)$, i.e. electrically:

Let N be a C -bicomodule. A \mathbb{K} -linear morphism $d : N \rightarrow C$ is called a coderivation if $\Delta_C \circ d = (d \otimes id_C) \circ \omega_N^r + (id_C \otimes d) \circ \omega_N^l$, i.e. electrically:

Proposition 1.3.2. Let V be a \mathbb{K} -module and M be a $T(V)$ -bimodule. A \mathbb{K} -linear morphism $f : V \rightarrow M$ uniquely determines a derivation $d_f : T(V) \rightarrow M$, i.e. there is an isomorphism $Hom_{\mathbb{K}}(V, M) \simeq Der(T(V), M)$.

Let N be a $T^c(V)$ -cobimodule. A \mathbb{K} -linear morphism $g : M \rightarrow V$ uniquely determines a coderivation $d_g^c : N \rightarrow T^c(V)$, i.e. there is an isomorphism $Hom_{\mathbb{K}}(N, V) \simeq Coder(N, T^c(V))$.

Proof. Let $a_1 \otimes \dots \otimes a_n$ be an elementary tensor of $T(V)$. We define $d_f(a_1 \otimes \dots \otimes a_n) = \sum_{i=1}^n a_1 \dots f(a_i) \dots a_n$ and $d_f(1) = 0$. Notice that d_f is by definition a derivation.

Restriction to V gives the natural isomorphism. Let $i : V \rightarrow T(V)$, then $i^* d_f = f$. Let $d : T(V) \rightarrow M$ be a derivation, then $d_i^* d = d$. Suppose that $g : M \rightarrow N$ is a morphism between $T(V)$ -bimodules, then naturality follows from bi-linearity.

In the dual case, d_g^c is a bit tricky to define. Let $\omega_N^l : N \rightarrow N \otimes T^c(V)$ and $\omega_N^r : N \rightarrow T^c(V) \otimes N$ denote the coactions on N . Since $T^c(V)$ is conilpotent we get the same kind of finiteness restrictions on N . We define the reduced coactions as $\bar{\omega}_N^l = \omega_N^l - _ \otimes 1$ and $\bar{\omega}_N^r = \omega_N^r - 1 \otimes _$, this is well-defined by coassociativity. Observe that for any $n \in N$ there are $k, k' > 0$ such that $\bar{\omega}_N^l(n) = 0$ and $\bar{\omega}_N^r(n) = 0$.

Let $n_{(k)}^{(i)}$ denote the extension of n by k coactions at position i , i.e. $n_{(k)}^{(i)} = \bar{\omega}_N^r \bar{\omega}_N^l(n)$. The extension of n by k coactions is then the sum over every position i , $n_{(k)} = \sum_{i=0}^k n_{(k)}^{(i)}$. Observe that $n_{(0)} = n$. The grade of n may be thought of as the smallest k such that $n_{(k)}$ is zero. This grading gives us the coradical filtration of N , and it is exhaustive by the finiteness restrictions given above. So every element of N may be given a finite grade.

If $g : N \rightarrow V$ is a linear map, we may think of it as a map sending every element of N to an element of $T^c(V)$ of grade 1. To get a map which sends element of grade k to grade k , we must extend the morphism. Let $\pi : T^c(V) \rightarrow V$ be the linear projection and define $g_{(k)}^{(i)} = \pi \otimes \dots \otimes \pi \circ g \otimes \pi$ as a morphism which is g at the i -th argument, but the projection otherwise. d_g^c is then defined as the sum over each coaction and coordinate.

$$d_g^c(n) = \sum_{k=0}^{\infty} \sum_{i=0}^k g_{(k)}^{(i)}(n_{(k)}^{(i)})$$

Upon closer inspection we may observe that this is the dual construction of the derivation morphism. It is well-defined as the sum is finite by the finiteness restrictions. The map is a coderivation by duality, and the natural isomorphism is given by composition with the projection map π . \square

Definition 1.3.3 (Differential algebra). Let A be an algebra. We say that A is a differential algebra if it is equipped with at least one derivation $d : A \rightarrow A$. Dually, a coalgebra C is called differential if it is equipped with at least one coderivation $d : C \rightarrow C$.

Definition 1.3.4 (A -derivation). Let (A, d_A) be a differential algebra and M a left A -module. A \mathbb{K} -linear morphism $d_M : M \rightarrow M$ is called an A -derivation if $d_M(am) = d_A(a)m + ad_M(m)$, or electrically:

Dually, given a differential coalgebra (C, d_C) and N a left C -comodule, a \mathbb{K} -linear morphism $d_N : N \rightarrow N$ is a coderivation if $\omega_N \circ d_N = (d_C \otimes id_N + id_C \otimes d_N) \circ \omega_N$, or electrically:

Proposition 1.3.5. Let A be a differential algebra and M a \mathbb{K} -module. A \mathbb{K} -linear morphism $f : M \rightarrow A \otimes_{\mathbb{K}} M$ uniquely determines a derivation $d_f : A \otimes M \rightarrow A \otimes M$, i.e. there is an isomorphism $Hom_{\mathbb{K}}(M, A \otimes_{\mathbb{K}} M) \simeq Der(A \otimes_{\mathbb{K}} M)$. Moreover, d_f is given as $(\nabla_A \otimes id_M) \circ (id_A \otimes f) + d_A \otimes id_M$.

Dually, if C is a differential coalgebra and N is a \mathbb{K} -module, then a \mathbb{K} -linear morphism $g : C \otimes N \rightarrow N$ uniquely determines a coderivation $d_g : C \otimes_{\mathbb{K}} N \rightarrow C \otimes_{\mathbb{K}} N$. There is an isomorphism $Hom_{\mathbb{K}}(C \otimes_{\mathbb{K}} N, N) \simeq Coder(C \otimes_{\mathbb{K}} N)$, and d_g is given as $(id_C \otimes g) \circ (\Delta_C \otimes id_N) + d_C \otimes id_N$.

Proof. ... \square

Recall that a module M^* is \mathbb{Z} graded if it decomposes as a sum $M^* = \bigoplus_{z \in \mathbb{Z}} M^z$. Let M^*, N^* be graded modules and $f : M^* \rightarrow N^*$ is a homogenous \mathbb{K} -linear morphism of degree n if it preserves the grading, that is $f(M^i) \subseteq N^{n+i}$. We denote the degree of f as $|f|$. The category of graded modules will be denoted as $GrMod_{\mathbb{K}}$ or $Mod_{\mathbb{K}}^*$. Generally \mathcal{C}^* is the category of graded objects whenever it makes sense, and the graded \mathbb{K} -module of morphisms between two graded objects is denoted as $Hom_{\mathbb{K}}^*(M^*, N^*)$.

M^\bullet is called a chain complex if it comes equipped with a homogenous morphism of degree 1, like $d_M^\bullet : M^\bullet \rightarrow M^\bullet$, such that $d_M^{\bullet 2} = 0$. This morphism is called differential. A chain morphism $f : M^\bullet \rightarrow N^\bullet$ is a homogenous \mathbb{K} -linear morphism of degree 0, such that $f \circ d_M^\bullet = d_N^\bullet \circ f$. The category of chain complexes will be denoted as $ChMod_{\mathbb{K}}$ or $Mod_{\mathbb{K}}^\bullet$. Generally \mathcal{C}^\bullet is the category of chain complexes whenever it makes sense, and the \mathbb{K} -module of morphisms between two chain complexes is denoted as $Hom_{\mathbb{K}}^\bullet(M^\bullet, N^\bullet)$.

The functor $_{[n]} : Mod_{\mathbb{K}}^\bullet \rightarrow Mod_{\mathbb{K}}^\bullet$ shifts the degree on each object by adding n to each grade, it is called the shift functor. Let \otimes denote the total tensor product in $Mod_{\mathbb{K}}^\bullet$. There is an isomorphism between the identity shift functor and total tensor of the stalk of \mathbb{K} , $_{[0]} \simeq \bar{\mathbb{K}} \otimes _$. In the same manner, shifting n -fold becomes isomorphic to tensoring with the shifted stalk of \mathbb{K} , $_{[n]} \simeq \bar{\mathbb{K}}[n] \otimes _$. For our purposes we will let $(A^\bullet, d_A^\bullet)[n] = (A^{\bullet+n}, -d_A^{\bullet+n})$. The koszul sign rule gives us a switching map for the tensor product. Thus, if $f^* : A^\bullet \rightarrow B^\bullet$ is a morphism of degree k , then $f^*[n] = (-1)^{k \cdot n} f^{*+n}$.

In electric diagrams we will write triangles for the differential if there are no ambiguity.

Proposition 1.3.6. *Let M^\bullet and N^\bullet be two chain complexes. The graded module of morphisms $Hom_{\mathbb{K}}^*(M^\bullet, N^\bullet)$ is a chain complex, given by the differential $\partial(f) = d_N^\bullet \circ f - (-1)^{|f|} f \circ d_M^\bullet$.*

Proof. We observe that $\partial : Hom_{\mathbb{K}}^*(M^\bullet, N^\bullet) \rightarrow Hom_{\mathbb{K}}^*(M^\bullet, N^\bullet)$ is a morphism of degree 1. It remains to check that $\partial^2 = 0$. Pick any homogenous morphism $f : M^\bullet \rightarrow N^\bullet$.

$$\begin{aligned} \partial^2(f) &= \partial(d_N^\bullet \circ f - (-1)^{|f|} f \circ d_M^\bullet) = \partial(d_N^\bullet \circ f) - (-1)^{|f|} \partial(f \circ d_M^\bullet) \\ &= -(-1)^{|d_N^\bullet \circ f|} d_N^\bullet \circ f \circ d_M^\bullet - (-1)^{|f|} d_N^\bullet \circ f \circ d_M^\bullet = 0 \end{aligned}$$

□

In an electric diagram we write ∂f as a sum of circuits.

Observe that $f : M^\bullet \rightarrow N^\bullet$ of degree 0 is a chain morphism if and only if $\partial(f) = 0$. We then observe that $\text{Hom}_{\mathbb{K}}^\bullet(M^\bullet, N^\bullet) \simeq Z^0 \text{Hom}_{\mathbb{K}}^*(M^\bullet)$.

To complete the definitions of graded modules and chain complexes to algebras we would like the structure morphisms to respect the given structure. E.g. if a and b are homogenous elements, we would like that the degree of ab is the sum of its parts, i.e. $|ab| = |a| + |b|$. Since multiplication by identity doesn't do anything, we want that the identity lives in the 0'th degree, and so forth.

Definition 1.3.7 (Graded algebra). Let A^\bullet be a graded \mathbb{K} -module. We say that A^\bullet is a graded algebra if A^\bullet is an algebra such that ∇_A and v_A are homogenous and of degree 0. Dually, C^\bullet is a graded coalgebra if Δ_C and ε_C are homogenous and of degree 0.

Definition 1.3.8 (Differential graded algebra). Let A^\bullet be a chain complex over \mathbb{K} . We say that A^\bullet is a differential graded algebra, or dg algebra, if it is a graded algebra and the differential is a graded derivation, i.e. $d_A(ab) = d_A(a)b + (-1)^{|a|}ad_A(b)$.

Dually, C^\bullet is a differential graded coalgebra if C^\bullet is a graded coalgebra and the differential is a graded coderivation.

1.4 Convolution Algebras

Let C be a coalgebra and A an algebra, then if $f, g : C \rightarrow A$ are \mathbb{K} -linear morphism we may define $f \star g = \nabla_A(f \otimes g)\Delta_C$. We call the operation \star for convolution.

$$f \star g = \begin{array}{c} \diagup \quad \diagdown \\ \textcircled{f} \quad \textcircled{g} \\ \diagdown \quad \diagup \end{array}$$

Proposition 1.4.1 (Convolution algebra). *The \mathbb{K} -module $\text{Hom}_{\mathbb{K}}(C, A)$ is an associative algebra when equipped with convolution $\star : \text{Hom}_{\mathbb{K}}(C, A) \rightarrow \text{Hom}_{\mathbb{K}}(C, A)$. The unit is given by $1 \mapsto v_A \circ \varepsilon_C$.*

Proof. This proposition follows from (co)associativity and (co)unitality of (C, A) .

$$(f \star g) \star h = \begin{array}{c} \diagup \quad \diagdown \\ \textcircled{f} \quad \textcircled{g} \quad \textcircled{h} \\ \diagdown \quad \diagup \end{array} = \begin{array}{c} \diagup \quad \diagdown \\ \textcircled{f} \quad \textcircled{g} \quad \textcircled{h} \\ \diagdown \quad \diagup \end{array} = \begin{array}{c} \diagup \quad \diagdown \\ \textcircled{f} \quad \textcircled{g} \quad \textcircled{h} \\ \diagdown \quad \diagup \end{array} = f \star (g \star h)$$

$$(v_A \circ \varepsilon_C) \star f = \text{diagram} = \text{diagram} = \text{diagram} = f \star (v_A \circ \varepsilon_C)$$

□

If A is an algebra and C is a coalgebra, then they may be given the structure of a differential algebra by attaching the 0 morphism to each algebra as the (co)derivation. In this case proposition 1.3.5 says that a morphism $f : M \rightarrow A \otimes_{\mathbb{K}} M$ determines the derivation given as $d_f = (\nabla_A \otimes id_M) \circ (id_A \otimes f)$. Dually, a morphism $g : C \otimes_{\mathbb{K}} M \rightarrow M$ determines the coderivation $d_g = (id_C \otimes g) \circ (\Delta_C \otimes id_N)$.

If $\alpha : C \rightarrow A$ is a \mathbb{K} -linear morphism, then there are two ways to extend α to obtain a (co)derivation. Precomposing with C 's comultiplication gives us a morphism from C to the free A -module $A \otimes_{\mathbb{K}} C$.

$$(\alpha \otimes id_C) \circ \Delta_C : C \rightarrow A \otimes_{\mathbb{K}} C$$

Postcomposing with A 's multiplication gives us a morphism from to the cofree C -comodule $C \otimes_{\mathbb{K}} A$ to A .

$$\nabla_A \circ (\alpha \otimes id_A) : C \otimes_{\mathbb{K}} A \rightarrow A$$

Notice that when applying proposition 1.3.5 to both morphisms yields the same map, and it is thus both a derivation and a coderivation.

$$d_\alpha = (\nabla_A \otimes id_C) \circ (id_A \otimes \alpha \otimes id_C) \circ (id_A \otimes \Delta_C)$$

$$d_\alpha = \text{diagram}$$

Proposition 1.4.2. $d_{(-)} : Hom_{\mathbb{K}}(C, A) \rightarrow End(C \otimes_{\mathbb{K}} A)$ is a morphism of algebras. Moreover, if $\alpha \star \alpha = 0$, then $d_\alpha^2 = 0$.

Proof. The proof quickly follows from (co)associativity and (co)unitality.

$$d_{\alpha \star \beta} = \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } \alpha \text{ and } \beta. \end{array} = \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } \alpha \text{ and } \beta, \text{ with a different internal structure.} \end{array} = d_{\alpha} \circ d_{\beta}$$

$$d_{v_{A \otimes \mathbb{K} C}} = \begin{array}{c} \text{Diagram: A vertical line with a small loop at the bottom.} \end{array} = \begin{array}{c} \text{Diagram: Two parallel vertical lines.} \end{array} = id_{C \otimes \mathbb{K} A}$$

□

Suppose that C and A are differential graded (co)algebras. We want to expect that the differential ∂ makes $Hom_{\mathbb{K}}^*(C, A)$ into a dg-algebra.

Proposition 1.4.3. *The convolution algebra $(Hom_{\mathbb{K}}^*(C, A), \star)$ is a dg-algebra with differential ∂ .*

Proof. We know that $(Hom_{\mathbb{K}}^*(C, A), \star)$ is a convolution algebra and that $(Hom_{\mathbb{K}}^*(C, A), \partial)$ is a chain complex. It remains to verify that the differential is compatible with the multiplication, i.e. $\partial(f \star g) = \partial f \star g + (-1)^{|f|} f \star \partial g$.

Let $f, g \in Hom_{\mathbb{K}}^*(C, A)$ be two homogenous morphisms. The key property to arrive at the result is that the differential in a dg-(co)algebra is a (co)derivation. We denote the degree of $f \star g$ as $|f \star g| = |f| + |g| = d$

$$\begin{aligned} \partial(f \star g) &= \partial \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } f \text{ and } g. \end{array} = \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } f \text{ and } g, \text{ with a downward arrow at the bottom.} \end{array} - (-1)^d \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } f \text{ and } g, \text{ with an upward arrow at the top.} \end{array} \\ &= \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } f \text{ and } g, \text{ with a downward arrow at the bottom of } f. \end{array} + (-1)^{|f|} \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } f \text{ and } g, \text{ with a downward arrow at the bottom of } g. \end{array} - (-1)^d ((-1)^{|g|} \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } f \text{ and } g, \text{ with an upward arrow at the top of } f. \end{array} + \begin{array}{c} \text{Diagram: A diamond shape with two internal nodes labeled } f \text{ and } g, \text{ with an upward arrow at the top of } g. \end{array}) \end{aligned}$$

$$\begin{aligned}
&= \text{Diagram 1} - (-1)^{|f|} \text{Diagram 2} + (-1)^{|f|} (\text{Diagram 3} - (-1)^{|g|} \text{Diagram 4}) \\
&= \text{Diagram 5} + (-1)^{|f|} \text{Diagram 6} = \partial(f) \star g + (-1)^{|f|} f \star \partial(g)
\end{aligned}$$

□

1.5 Twisting Morphisms

In this section we will define twisting morphisms from coalgebras to algebras. They are of importance as the bifunctor $Tw(C, A)$ is represented in both arguments. To understand the elements of Tw we start this section by reviewing the Maurer-Cartan equation.

Suppose that C is a dg-coalgebra and A is a dg-algebra. We say that a morphism $\alpha \in Hom_{\mathbb{K}}^*(C, A)$ is twisting if it is of degree -1 and satisfies the Maurer-Cartan equation:

$$\partial\alpha + \alpha \star \alpha = 0.$$

We say that α is an element of $Tw(C, A) \subset Hom_{\mathbb{K}}^{-1}(C, A) \subset Hom_{\mathbb{K}}^*(C, A)$. In light of proposition 1.4.2, every morphism between coalgebras and algebras extends to a unique (co)derivation on the tensor product $C \otimes_{\mathbb{K}} A$. Let d_{α}^r denote this unique morphism. In the case of dg-coalgebras and dg-algebras we perturbate the total differential on the tensor with d_{α}^r , as in proposition 1.3.5. We call this derivation for the perturbed derivative.

$$d_{\alpha}^{\bullet} = d_{C \otimes_{\mathbb{K}} A}^{\bullet} + d_{\alpha}^r = d_C^{\bullet} \otimes id_A + id_C \otimes d_A^{\bullet} + d_{\alpha}^r$$

Proposition 1.5.1. *Suppose that C is a dg-coalgebra and A is a dg-algebra, and $\alpha \in Hom_{\mathbb{K}}^*(C, A)$. The perturbed derivation satisfies the following relation.*

$$d_{\alpha}^{\bullet 2} = d_{\partial\alpha + \alpha \star \alpha}^r$$

Moreover, a morphism is twisting if and only if the perturbed derivative is a differential.

Proof. $d_{\alpha}^{\bullet 2} = d_{C \otimes_{\mathbb{K}} A}^{\bullet} \circ d_{\alpha}^r + d_{\alpha}^r \circ d_{C \otimes_{\mathbb{K}} A}^{\bullet} + d_{\alpha}^{r 2}$. By proposition 1.4.2 d_{α}^r is an algebra homomorphism from the convolution algebra to the endomorphism algebra, thus $d_{\alpha}^{r 2} = d_{\alpha \star \alpha}^r$.

$$\begin{aligned}
d_{C \otimes_{\mathbb{K}} A}^{\bullet} \circ d_{\alpha}^r &= \text{Diagram 1} + \text{Diagram 2} - \text{Diagram 3} \\
d_{\alpha}^r \circ d_{C \otimes_{\mathbb{K}} A}^{\bullet} &= -\text{Diagram 4} + \text{Diagram 5} + \text{Diagram 6}
\end{aligned}$$

By summing the above terms we get

$$d_{C \otimes_{\mathbb{K}} A}^{\bullet} \circ d_{\alpha}^r + d_{\alpha}^r \circ d_{C \otimes_{\mathbb{K}} A}^{\bullet} = d_{d_C^{\bullet} \circ \alpha + \alpha \circ d_A^{\bullet}}^r = d_{\partial \alpha}^r,$$

to obtain the result.

$$d_{\alpha}^{\bullet^2} = d_{C \otimes_{\mathbb{K}} A}^{\bullet} \circ d_{\alpha}^r + d_{\alpha}^r \circ d_{C \otimes_{\mathbb{K}} A}^{\bullet} + d\alpha^{r^2} = d_{\partial \alpha}^r + d_{\alpha \star \alpha}^r = d_{\partial \alpha + \alpha \star \alpha}$$

□

Corollary 1.5.1.1. *If $\alpha : C \rightarrow A$ is a twisting morphism, then $(C \otimes_{\mathbb{K}} A, d_{\alpha}^{\bullet})$ is a chain complex. It is called the right twisted tensor product and is denoted as $C \otimes_{\alpha} A$.*

Normally $A \otimes C$ and $C \otimes A$ are isomorphic as modules. In general, it is not true that $C \otimes_{\alpha} A$ and $A \otimes_{\alpha} C$ are isomorphic, since we choose a particular side to perform the twisting. However, if A is commutative and C is cocommutative then they are isomorphic. To illustrate we realize the unique derivation above as a right derivative. The left derivative d_{α}^l is then defined analogously.

$$d_{\alpha}^l = \text{Diagram}$$

Remark 1.5.2. Functoriality of \otimes_{α} is obtained from the category of elements. I propose that there is an equivalence of categories, that is:

$$\int_{(C,A)} Tw(C, A) \simeq \text{right twisted tensors.}$$

1.6 Bar and Cobar Construction

The bar and cobar construction has been subjected to abstraction many times since its creation (Reference here!). The bar construction was made by MacLane and Moore in the 50s (Reference here!). It's dual, the cobar construction was made by Adams (reference here! Jeg har kildene på lesesal, lover) to complement their work. We will mainly follow the work of [1] to obtain the bar and cobar construction. The approach which we are going to take is slightly inspired by MacLanes[2] canonical resolutions of comonads.

For our purposes, the bar construction of an augmented algebra is a simplicial resolution with the cofree coalgebra structure. For a dg-algebra, we will realize this resolution as the total complex of its resolution. Dually, the cobar construction of a conilpotent coalgebra is a cosimplicial resolution with the free algebra structure. We will see that these constructions defines an adjoint pair of functors.

Definition 1.6.1. The simplex category Δ consists of ordered sets $[0] = \emptyset$ and $[n] = \{1, \dots, n\}$ for any $n \in \mathbb{N}$. A morphism is a monotone function between the sets.

Δ^+ is the full subcategory of Δ where $n > 0$. Δ_+ is the wide subcategory of Δ with only injective functions.

The simplex category comes equipped with coface and codegeneracy morphisms. The coface maps are the injective morphisms $\delta_i : [n] \rightarrow [n+1]$, and the codegeneracy maps are the surjective morphisms $\sigma_i : [n] \rightarrow [n-1]$.

$$\delta_i(k) = \begin{cases} k, & \text{if } k < i \\ k+1, & \text{otherwise} \end{cases} \quad \sigma_i(k) = \begin{cases} k, & \text{if } k \leq i \\ k-1, & \text{otherwise} \end{cases}$$

Every morphism in Δ may be realized as a composition of coface and codegeneracy maps, see [2]. Furthermore, these maps are characterized by some identities, called the cosimplicial identities.

1. $\delta_j \delta_i = \delta_i \delta_{j-1}$, if $i < j$
2. $\sigma_j \delta_i = \delta_i \sigma_{j-1}$, if $i < j$
3. $\sigma_j \delta_i = id$, if $i = j$ or $i = j + 1$
4. $\sigma_j \delta_i = \delta_{i-1} \sigma_j$, if $i > j + 1$
5. $\sigma_j \sigma_i = \sigma_i \sigma_{j+1}$, if $i \leq j$

We may arrange the arrows of the simplex category in the following way:

$$\begin{array}{ccccccc} [0] & \longrightarrow & [1] & \xrightarrow{\delta_i} & [2] & \xrightarrow{\delta_i} & [3] & \xrightarrow{\delta_i} & \dots \\ & & & & & & & & \\ [0] & & [1] & \xleftarrow{\sigma_1} & [2] & \xleftarrow{\sigma_i} & [3] & \xleftarrow{\sigma_i} & \dots \end{array}$$

Let \mathcal{C} be a category. A simplicial object in \mathcal{C} is a functor $S : (\Delta^+)^{op} \rightarrow \mathcal{C}$. It may be viewed as a collection of objects $\{S_n\}_{n \in \mathbb{N}^+}$ together with face maps $d^i : S_n \rightarrow S_{n-1}$ and degeneracy maps $s^i : S_n \rightarrow S_{n+1}$ satisfying the simplicial identities. An augmented simplicial object is a functor $S : \Delta^{op} \rightarrow \mathcal{C}$. The restricted functor $S^+ : (\Delta^+)^{op} \rightarrow \mathcal{C}$ is the augmentation ideal of S . An augmented semi-simplicial object is a functor $S : (\Delta_+)^{op} \rightarrow \mathcal{C}$. Dually, a cosimplicial object is a functor $S : \Delta^+ \rightarrow \mathcal{C}$, it may be regarded as a sequence of objects with coface and codegeneracy maps satisfying the cosimplicial identities.

Let \mathcal{A} be an abelian category. To each semi-simplicial object $M : (\Delta_+^+)^{op} \rightarrow \mathcal{A}$ there is an associated chain complex M^\bullet . Let $M^\bullet = \bigoplus_{i=1}^{\infty} M[i]$ with differential $d_M^n = \sum_{i=1}^n (-1)^{i-1} d^i$. This differential is well-defined by simplicial identity 1.

$$\dots \longrightarrow M_3 \xrightarrow{d^1-d^2+d^3} M_2 \xrightarrow{d^1-d^2} M_1 \xrightarrow{0} 0 \longrightarrow \dots$$

As face maps and degeneracy maps have the same identities, but flipped around, we could also have defined a chain complex by using the degeneracies instead.

The simplex category has a universal monoid. Let $+$: $\Delta \rightarrow \Delta$ be a functor acting on objects and morphisms as:

$$[m] + [n] = [m + n]$$

$$(f + g)(k) = \begin{cases} f(k), & \text{if } k \leq m \\ g(k) + m, & \text{otherwise} \end{cases}$$

Notice that $[0] + _ \simeq Id_\Delta$, so $(\Delta, +, [0])$ is a monoidal category. Since $[1]$ is terminal in Δ it becomes a monoid with $\delta_0 : [0] \rightarrow [1]$ as unit and $\sigma_1 : [2] \rightarrow [1]$ as multiplication. Associativity and unitality is satisfied by uniqueness of morphisms $f : [n] \rightarrow [1]$.

Proposition 1.6.2. *Let $(\mathcal{C}, \otimes, Z)$ be a monoidal category. If (\mathcal{C}, η, μ) is a monoid in \mathcal{C} , then there is a strong monoidal functor $F : \Delta \rightarrow \mathcal{C}$, such that $F[1] \simeq C$, $F\delta_0 \simeq \eta$ and $F\sigma_1 \simeq \mu$.*

An algebra A is a monoid in the monoidal category $(Mod_{\mathbb{K}}, \otimes_{\mathbb{K}}, \mathbb{K})$. By proposition 1.6.2 we may think of A as an augmented cosimplicial object $A : \Delta \rightarrow Mod_{\mathbb{K}}$. Notice that all of the cosimplicial identities follow from associativity and unitality. If A is an augmented algebra, we may instead give it the structure of an augmented simplicial set. Let $d_1^1 = \varepsilon_A$ be the augmentation. We define $d_n^n = A^{\otimes n-1} \otimes \varepsilon_A$ and set $d_n^i = A^{i-1} \otimes \nabla_A \otimes A^{\otimes n-i-1}$. All the degeneracies are set to be the units, i.e. $s_n^i = A^{\otimes i} \otimes v_A \otimes A^{\otimes n-i-1}$. One may check that this structure defines a simplicial object $A : \Delta^{op} \rightarrow Mod_{\mathbb{K}}$. Observe that the associated chain complex A^\bullet is exactly the Hochschild complex of A . We depict the simplicial object as the following diagram:

$$\begin{array}{ccccccc} \mathbb{K} & \xleftarrow{\varepsilon_A} & A & \xleftarrow[A \otimes \varepsilon_A]{\nabla_A} & A^{\otimes 2} & \xleftarrow[A^{\otimes 2} \otimes \varepsilon_A]{\nabla_A} & A^{\otimes 3} & \xleftarrow[A^{\otimes 4} \otimes \varepsilon_A]{\nabla_A} & \dots \\ & & & & & & & & \\ \mathbb{K} & & A & \xrightarrow{s^1} & A^{\otimes 2} & \xrightarrow{s^i} & A^{\otimes 3} & \xrightarrow{s^i} & \dots \end{array}$$

The augmentation ideal \bar{A} carries a natural semi-simplicial structure induced by A . By restricting each of the face maps $\bar{d}^i = d^i|_{\bar{A}} : \bar{A}^{\otimes n} \rightarrow \bar{A}^{\otimes n-1}$ we obtain the maps together with the simplicial identity 1. This is the non-unital Hochschild complex of A . We may depict the semi-simplicial object as the following diagram:

$$\mathbb{K} \xleftarrow{0} \bar{A} \xleftarrow[\underset{0}{\parallel}]{\nabla_A} \bar{A}^{\otimes 2} \xleftarrow[\underset{0}{\parallel}]{\nabla_A} \bar{A}^{\otimes 3} \xleftarrow[\underset{0}{\parallel}]{\nabla_A} \dots$$

Notice that as graded modules, the chain complex \bar{A}^\bullet is isomorphic to $T^c(\bar{A})$. We will now instead consider the suspended non-unital algebra $\bar{A}[1]$. Every algebra may be considered as a graded algebra concentrated in degree 0, the shift functor then recontextualize the degree the algebra is concentrated in. With Koszul sign rule, we may define the suspended multiplication as $\nabla_{A[1]}(a_1 \otimes a_2) = (-1)^{|a_1|} a_1 a_2$. Notice that $\nabla_{A[1]}$ is a morphism of degree -1 . Repeating Koszul sign rule, we may see that associativity does not longer hold, as multiplying the multiplication on the right first introduces a sign, contrary to first multiplying on the left side.

Proposition 1.6.3. *The suspended augmentation ideal $\bar{A}[1]$ is a semi-simplicial set with face maps:*

$$\bar{d}^i = (-1)^{i-1} d^i = (-1)^{i-1} (\nabla_{A[1]})_{(i-1)}^{(n-1)}.$$

Corollary 1.6.3.1. *The differential $d_{\bar{A}[1]}^\bullet$ is a coderivation for the cofree coalgebra $T^c(\bar{A}[1])$. Thus $(\bar{A}[1]^\bullet, d_{\bar{A}[1]}^\bullet)$ is a dg-coalgebra.*

Proof. The differential is given by the alternating sum of face maps.

$$d_{\bar{A}[1]}^n = \sum_{i=1}^n (-1)^{i-1} \bar{d}^i = \sum_{i=1}^n (-1)^{2(i-1)} d^i = \sum_{i=1}^n (\nabla_{A[1]})_{(i-1)}^{(n-1)}$$

By injecting $\bar{A}[1]$ into $T^c(\bar{A}[1])$ we may think of $\nabla_{\bar{A}[1]} : \bar{A}[1]^{\otimes 2} \rightarrow T^c(\bar{A}[1])$ as a morphism into the tensor coalgebra. By using proposition 1.3.2, $\nabla_{\bar{A}[1]}$ extends uniquely into a coderivation:

$$d_{\bar{A}[1]}^c = \sum_{n=0}^{\infty} \sum_{i=0}^n (\nabla_{\bar{A}[1]})_{(i)}^{(n)} = d_{\bar{A}[1]}^\bullet.$$

□

If (A, d_A^\bullet) is an augmented dg-algebra, then A is a simplicial object of $Mod_{\mathbb{K}}^\bullet$. It has an associated chain complex. Taking the alternate sum of face maps gives us a double complex as below. We define the double complex A^\bullet as the associated chain complex to A .

$$\begin{array}{ccccccc}
& \vdots & & \vdots & & \vdots & \\
& \nabla_A \downarrow \downarrow \downarrow A^{\otimes 2} \otimes \varepsilon_A & \nabla_A \downarrow \downarrow \downarrow A^{\otimes 2} \otimes \varepsilon_A & \nabla_A \downarrow \downarrow \downarrow A^{\otimes 2} \otimes \varepsilon_A & & & \\
\cdots & \xrightarrow{d_{A^{\otimes 2}}^\bullet} & (A^{\otimes 2})^1 & \xrightarrow{d_{A^{\otimes 2}}^\bullet} & (A^{\otimes 2})^0 & \xrightarrow{d_{A^{\otimes 2}}^\bullet} & (A^{\otimes 2})^{-1} \xrightarrow{d_{A^{\otimes 2}}^\bullet} \cdots \\
& \nabla_A \downarrow \downarrow A \otimes \varepsilon_A & \nabla_A \downarrow \downarrow A \otimes \varepsilon_A & \nabla_A \downarrow \downarrow A \otimes \varepsilon_A & & & \\
\cdots & \xrightarrow{d_A^\bullet} & A^1 & \xrightarrow{d_A^\bullet} & A^0 & \xrightarrow{d_A^\bullet} & A^{-1} \xrightarrow{d_A^\bullet} \cdots \\
& \downarrow \varepsilon_A & \downarrow \varepsilon_A & \downarrow \varepsilon_A & & & \\
\cdots & \xrightarrow{0} & 0 & \xrightarrow{0} & \mathbb{K} & \xrightarrow{0} & 0 \xrightarrow{0} \cdots
\end{array}$$

For simplicity we write d_1 for the horizontal differential and d_2 for the vertical differential. The total associated chain complex is the total complex for $Tot(A^\bullet)$, denoted A^\bullet if there are no confusion. In the case of the suspended algebra, the signs mess up commutativity of the squares, thus we change the sign of the horizontal differential to $(-1)^n$. We may also define the differential of the total complex simply as the sum of d_1 and d_2 .

Proposition 1.6.4. *Let A an augmented dg-algebra. The bar complex BA is the total associated chain complex $\bar{A}[1]^\bullet$ of the suspended augmentation ideal \bar{A} . (BA, d_{BA}^\bullet) is the cofree conilpotent coalgebra equipped with $d_{BA}^\bullet = d_1 + d_2$ as coderivation.*

Proof. It is apparent that d_1 and d_2 are coderivations with respect to deconcatenation. Since the multiplication ∇_A is a chain map $d_{BA}^2 = d_1 \circ d_2 + d_2 \circ d_1 = 0$. We will show this for each element in $A^{\otimes 2}$, then the result may be extended to all of BA .

$$\begin{aligned}
d_1 \circ d_2(a_1 \otimes a_2) &= (-1)^{|a_1|} d_1(a_1 a_2) = (-1)^{|a_1|} d_A^\bullet[1](a_1 a_2) \\
&= (-1)^{|a_1|+1} d_A^\bullet(a_1 a_2) = (-1)^{|a_1|+1} (d_A^\bullet(a_1) a_2 + (-1)^{|a_1|} a_1 d_A^\bullet(a_2)) \\
&= (-1)^{|a_1|+1} d_A^\bullet(a_1) a_2 - a_1 d_A^\bullet(a_2)
\end{aligned}$$

$$\begin{aligned}
d_2 \circ d_1(a_1 \otimes a_2) &= d_2 \circ (d_A^\bullet[1] \otimes id_{A[1]} + id_{A[1]} \otimes d_A^\bullet[1])(a_1 \otimes a_2) \\
&= -d_2 \circ (d_A^\bullet(a_1) \otimes a_2 + (-1)^{|a_1|+1} a_1 \otimes d_A^\bullet(a_2)) \\
&= (-1)^{|d_A^\bullet(a_1)|+1} d_A^\bullet(a_1) a_2 + (-1)^{2|a_1|+2} a_1 d_A^\bullet d_A^\bullet(a_2) \\
&= (-1)^{|a_1|} d_A^\bullet(a_1) a_2 + a_1 d_A^\bullet(a_2) = -d_1 \circ d_2(a_1 \otimes a_2)
\end{aligned}$$

□

Remark 1.6.5. For now we don't need to show that BA is a functor. This property follows from BA being the representing object of $Tw(_, A)$.

On the other hand, a coalgebra C is a comonoid in $Mod_{\mathbb{K}}$. By the dual of proposition 1.6.2 we may think of it as a simplicial object $C : (\Delta)^{op} \rightarrow Mod_{\mathbb{K}}$. Dually, all of the simplicial identities follows from coassociativity and counitality. A coaugmented coalgebra C may be given a cosimplicial structure in the opposite way of algebras. We then get that the coaugmentation quotient \bar{C} is a semi-cosimplicial object of $Mod_{\mathbb{K}}$. Observe that \bar{C} has an associated chain complex like \bar{A} , but every arrow goes in the opposite direction.

$$\begin{array}{ccccccc} \mathbb{K} & \xrightarrow{v_C} & C & \xrightleftharpoons[A \otimes v_C]{\Delta_C} & C^{\otimes 2} & \xrightleftharpoons[C^{\otimes 2} \otimes v_C]{\Delta_C} & C^{\otimes 3} \xrightleftharpoons[C^{\otimes 4} \otimes v_C]{\Delta_C} \dots \\ & & & & & & \\ \mathbb{K} & & C & \xleftarrow{s_1} & C^{\otimes 2} & \xleftarrow{s_i} & C^{\otimes 3} \xleftarrow{s_i} \dots \end{array}$$

The cobar construction is made from the inverse shifted, or desuspended coalgebra $C[-1]$. We realize it as the free tensor algebra $T(\bar{C}[-1])$, where the comultiplication $\Delta_{\bar{C}[-1]}$ induces a derivation $d_{\bar{C}[-1]}$ by proposition 1.3.2.

Remark 1.6.6. As we have chosen to define $\nabla_{A[1]}(a_1 \otimes a_2) = (-1)^{|a_1|} a_1 a_2$, we are forced by the linear dual to define $\Delta_{C[-1]}(c) = -(-1)^{|c(1)|} c_{(1)} \otimes c_{(2)}$.

Proposition 1.6.7. *Let C be a coaugmented dg-coalgebra. The cobar complex ΩC is the total associated chain complex $\bar{C}[-1]^{\bullet}$ of the desuspended coaugmentation quotient \bar{C} . $(\Omega C, D_{\Omega C}^{\bullet})$ is the free algebra equipped with $d_{\Omega C}^{\bullet} = d_1 + d_2$ as derivation.*

We will now see that the bar and cobar construction defines an adjoint pair of functors. Note that since for any conilpotent dg-coalgebra C , the object ΩC represents the functor in the category of augmented algebras. By Yoneda's lemma, the data of morphisms are then defined, so Ω does truly define a functor.

Theorem 1.6.8. *Let C be a conilpotent dg-coalgebra and A an augmented dg-algebra. The functor $Tw(C, A)$ is represented in both arguments, i.e.*

$${}_{Alg}^{Aug\bullet}(\Omega C, A) \simeq Tw(C, A) \simeq {}_{CoAlg}^{Conil\bullet}(C, BA).$$

Proof. We will show that ΩC represents the set of twisting morphisms in the first argument. Showing that BA represents the second argument uses every dual proposition. Thus, it is necessary that C is conilpotent, in order to dualize the arguments.

Suppose that $f : \Omega C \rightarrow A$ is an augmented dg-algebra homomorphism. f is then a morphism of degree 0. By freeness, f is uniquely determined by a morphism $f|_{\bar{C}[-1]} : \bar{C} \rightarrow \bar{A}$ of degree 0, which corresponds to a morphism $f' : C \rightarrow A$ of degree -1 .

Since f is a morphism of chain complexes it commutes with the differential, i.e.

$$\begin{aligned} f \circ d_{\Omega C}^{\bullet} &= d_A^{\bullet} \circ f \\ f \circ (d_1 + d_2) &= d_A^{\bullet} \circ f \end{aligned}$$

This is equivalent to say that $-f' \circ d_C^\bullet - f' \star f' = d_A^\bullet \circ f'$. Thus f' is a twisting morphism. \square

1.7 Strongly Homotopy Associative Algebras and Coalgebras

We have seen from corollary 1.6.3.1 that any algebra A defines a dg-coalgebra $T^c(A[1])$, the bar construction, with a coderivation m^c of degree -1 . Does this however work in reverse? I.e. if A is a vector space such that $T^c(A[1])$ with coderivation m^c is a dg-coalgebra, is then A an algebra. The answer to this is no, but it leads to the definition of a strongly homotopy associative algebra.

Definition 1.7.1. An A_∞ -algebra is a graded vector space A together with a differential $m : \bar{T}^c(A[1]) \rightarrow \bar{T}^c(A[1])$ that is a coderivation of degree -1 .

The differential m induces structure morphisms on $A[1]$. By proposition 1.3.2 there is a natural bijection $Hom_{\mathbb{K}}(\bar{T}^c(A[1]), A[1]) \simeq Coder(\bar{T}^c(A[1]), \bar{T}^c(A[1]))$ given by the projection onto $A[1]$. Thus $m : \bar{T}^c(A[1]) \rightarrow \bar{T}^c(A[1])$ corresponds to maps $\tilde{m}_n : A[1]^{\otimes n} \rightarrow A[1]$ of degree -1 for any $n \geq 1$. We define maps $m_n : A^{\otimes n} \rightarrow A$ by the composite $s^{-1}\tilde{m}_n s^{\otimes n}$. Since $s^{\otimes n}$ is of degree n , \tilde{m}_n and s^{-1} is of degree -1 , we get that m_n is of degree $n - 2$.

$$\begin{array}{ccc} A^{\otimes n} & \xrightarrow{m_n} & A \\ s^{\otimes n} \downarrow \simeq & & s^{-1} \uparrow \simeq \\ A[1]^{\otimes n} & \xrightarrow{\tilde{m}_n} & A[1] \end{array}$$

Proposition 1.7.2. An A_∞ -algebra is equivalent to a graded vector space A together with homogenous morphisms $m_n : A^{\otimes n} \rightarrow A$ of degree $n - 2$. Moreover, the morphism must satisfy the following relations for any $n \geq 1$:

$$(\text{rel}_n) \quad \sum_{p+q+r=n} (-1)^{p+qr} m_{p+1+r} \circ (id^{\otimes p} \otimes m_q \otimes id^{\otimes r}) = 0$$

Remark 1.7.3. We make a more convenient notation for (rel_n) , called partial composition \circ_i .

$$\begin{aligned} m_{p+1+r} \circ_{p+1} m_q &= m_k \circ (id^{\otimes p} \otimes m_q \otimes id^{\otimes r}) \\ (\text{rel}_n) \quad \sum_{p+q+r=n} (-1)^{p+qr} m_{p+1+r} \circ_{p+1} m_q &= 0 \end{aligned}$$

Before starting with the proof we will use a lemma for checking whether a coderivation $m : T^c(A) \rightarrow T^c(A)$ is a differential.

Lemma 1.7.4. Let $m : T^c(A) \rightarrow T^c(A)$ be a coderivation, and denote $m_n = m|_{A^{\otimes n}}$. m is a differential if and only if the following relations are satisfied:

$$\sum_{p+q+r=n} m_{p+1+r} \circ_{p+1} m_q = 0$$

Proof. By proposition 1.3.2 we may write $m = \sum_{n=0}^{\infty} \sum_{i=0}^n m_{(n)}^{(i)}$. By using partial composition, we rewrite its n 'th component as:

$$m_n = \sum_{q=1}^n \sum_{p=1}^n id^{\otimes(n-q)} \circ_p m_q = \sum_{p+q+r=n} id^{\otimes(p+1+r)} \circ_{p+1} m_q$$

For m^2 we denote its n 'th component as m_n^2 . Observe the following:

$$\begin{aligned} m_n^2 &= m \circ m_n = m \circ \sum_{p+q+r=n} id^{\otimes(p+1+r)} \circ_{p+1} m_q = \sum_{p+q+r=n} m \circ_{p+1} m_q \\ \pi m_n^2 &= \pi \sum_{p+q+r=n} m \circ_{p+1} m_q = \sum_{p+q+r=n} m_{p+1+r} \circ_{p+1} m_q \end{aligned}$$

Since every coderivation are uniquely determined by π , its projection onto A we get that $m^2 = 0$ if and only if

$$\sum_{p+q+r=n} m_{p+1+r} \circ_{p+1} m_q = 0.$$

□

Proof of proposition 1.7.2. Let (A, m) be an A_{∞} -algebra. We denote the n 'th component of m as \tilde{m}_n . The n 'th components thus define maps $m_n : A^{\otimes n} \rightarrow A$ as $m_n = s^{-1} \tilde{m}_n s^{\otimes n}$.

By the above lemma we know that the n 'th component of m^2 is:

$$\begin{aligned} &\sum_{p+q+r=n} \tilde{m}_{p+1+r} \circ_{p+1} \tilde{m}_q \\ &= \sum_{p+q+r=n} s m_{p+1+r} s^{-(p+1+r)} \circ_{p+1} s m_q s^{-q} = \sum_{p+q+r=n} (-1)^{pq+r} s m_{p+1+r} \circ_{p+1} m_q s^{-\otimes n} \end{aligned}$$

Since suspension and desuspension are isomorphism we get that $m^2 = 0$ if and only if (rel_n) are 0 for every $n \geq 1$, i.e.

$$\sum_{p+q+r=n} (-1)^{p+qr} m_{p+1+r} \circ_{p+1} m_q = 0$$

□

Given an A_{∞} algebra A we may either think of it as a differential tensor coalgebra $\bar{T}^c(A[1])$ with differential $m : \bar{T}^c(A[1]) \rightarrow \bar{T}^c(A[1])$ or as a graded vector space with morphisms $m_n : A^{\otimes n} \rightarrow A$ satisfying (rel_n) . We will calculate (rel_n) for 1, 2, 3:

$$\begin{aligned} (\text{rel}_1) \quad & m_1 \circ m_1 = 0 \\ (\text{rel}_2) \quad & m_1 \circ m_2 - m_2 \circ_1 m_1 - m_2 \circ_2 m_1 = 0 \\ (\text{rel}_3) \quad & m_1 \circ m_3 + m_2 \circ_1 m_2 - m_2 \circ_2 m_2 + m_3 \circ_1 m_1 + m_3 \circ_2 m_1 + m_3 \circ_3 m_1 = 0 \end{aligned}$$

We see that (rel_1) states that m_1 should be a differential, we may thus think of (A, m_1) as a chain complex. Furthermore, (rel_2) says that $m_2 : (A^{\otimes 2}, m_1 \otimes id_A + id_A \otimes m_1) \rightarrow (A, m_1)$ is a morphism of chain complexes. Lastly, (rel_3) gives us a homotopy for the associator of m_2 , namely m_3 . Thus we may regard (A, m_1, m_2) as an algebra which is associative up to homotopy. Regarding A as a chain complex instead we obtain our final definition of an A_∞ -algebra.

Proposition 1.7.5. *Suppose that (A, d) is a chain complex, and that there exists morphisms $m_n : A^{\otimes n} \rightarrow A$ for any $n \geq 2$. A is an A_∞ -algebra if and only if it satisfies the following relations:*

$$(\text{rel}'_n) \quad \partial(m_n) = - \sum_{\substack{n=p+q+r \\ k=p+1+r \\ k>1, q>1}} (-1)^{p+qr} m_k \circ_p + 1 m_q$$

We define the homotopy of an A_∞ -algebra to be the homology of the chain complex (A, m_1) . Since $\partial(m_3) = m_2 \circ_1 m_2 - m_2 \circ_2 m_2$, we get that m_2 is associative in homology. Thus for any A_∞ -algebra A , the homotopy HA is an associative algebra. The operadic homology of A is defined as the homology of $(T^c(A[1]), m)$, which is the non-unital augmented Hochschild homology of A .

Example 1.7.6. An associative dg-algebra is an A_∞ algebra with trivial higher morphisms.

Example 1.7.7. Eksemplet jeg fikk fra Torgeir.

A morphism between A_∞ -algebras is called an ∞ -morphism. Suppose that A and B are two A_∞ -algebras, an ∞ -morphism $f : A \rightsquigarrow B$ is a dg-coalgebra homomorphism $\tilde{f} : (\bar{T}^c(A[1]), m^A) \rightarrow (\bar{T}^c(B[1]), m^B)$. By proposition 1.3.2, \tilde{f} is uniquely determined by homogenous morphisms $f_n : A^{\otimes n} \rightarrow B$ of degree $n-1$ for any $n \geq 1$. f_1 is required to be a morphism of the chain complexes $f_1 : (A, m_1^A) \rightarrow (B, m_1^B)$. For any $n \geq 2$ f should satisfy the relations:

$$(\text{rel}_n) \quad \partial(f_n) = \sum_{\substack{p+1+r=k \\ p+q+r=n}} (-1)^{pq+r} f_k \circ_{p+1} m_q^A - \sum_{\substack{k \geq 2 \\ i_1 + \dots + i_k = n}} (-1)^e m_k^B \circ (f_{i_1} \otimes f_{i_2} \otimes \dots \otimes f_{i_k})$$

where e is given as: $e = (k-1)(i_1-1) + (k-2)(i_2-1) + \dots + 2(i_{k-2}-1) + (i_{k-1}-1)$

Since the composition of two dg-coalgebra homomorphism is again a dg-algebra homomorphism, we get that the composition of two ∞ -morphisms is again an ∞ -morphism. More explicitly if $f : A \rightsquigarrow B$ and $g : B \rightsquigarrow C$ are two ∞ -morphisms, then their composition is defined as:

$$(fg)_n = \sum_r \sum_{i_1 + \dots + i_r = n} (-1)^e g_r(f_{i_1} \otimes \dots \otimes f_{i_r}).$$

An ∞ -quasi-isomorphism is an ∞ -morphism f such that f_1 is a quasi-isomorphism.

Let Alg_∞ denote the category of A_∞ -algebras. The morphisms in this category are the ∞ -morphisms. Observe that the bar construction $B : \text{Alg}_\infty \rightarrow \text{ConilCoalg}^\bullet$ is a fully faithful functor, identifying Alg_∞ as a subcategory of $\text{ConilCoalg}^\bullet$.

Dual to A_∞ -algebras we got A_∞ -coalgebras. This will be th

Definition 1.7.8. A graded vector space C is called an A_∞ -coalgebra if it is a dg-algebra of the form $(\bar{T}(B[-1]), d)$ where d is a derivation of degree -1 . Dually, this is equivalent to a chain complex (B, d^1) , where d^1 is of degree 1, and together with morphisms $d^n : B \rightarrow B^{\otimes n}$. The morphism should satisfy the relations:

$$(\text{rel}_n) \quad \sum_{p+q+r=n} (-1)^{pq+r} d^{p+1+q} \circ_{p+1}^{op} d^q = 0$$

Chapter 2

Homotopy Theory of Algebras

Quillen envisioned a more general approach to homotopy theory, which he dubbed homotopical algebra. A homotopy theory was then enclosed by the structure of a model category, then a closed model category. Many of the results from classical homotopy theory was then recovered in this new setting of model categories. The theorem which we are concerned about is Whiteheads theorem:

Theorem 2.0.1 (Whiteheads Theorem). *Let X and Y be two CW-complexes. If $f : X \rightarrow Y$ is a weak equivalence, then it is also a homotopy equivalence. I.e. there exists a morphism $g : Y \rightarrow X$ such that $gf \sim id_X$ and $fg \sim id_Y$.*

If we employ Quillens model category onto the category Top , we get that a space X is bifibrant if and only if it is a CW-complex. The natural generalization is then to not ask of X to be a CW-complex, but a bifibrant object.

Theorem 2.0.2 (Generalized Whiteheads Theorem). *Let \mathcal{C} be a model category. Suppose that X and Y are bifibrant objects of \mathcal{C} , and that there is a weak-equivalence $f : X \rightarrow Y$. Then f is also a homotopy equivalence, i.e. there exists a morphism $g : Y \rightarrow X$ such that $gf \sim id_X$ and $fg \sim id_Y$.*

The category of differential graded (co)algebras employs such a model category. Here we let the weak-equivalences be quasi-isomorphisms. Moreover, in this case the bar and cobar construction is a Quillen equivalence between the model structures. As we will see, a dg-coalgebra will be bifibrant exactly when it is an A_∞ -algebra. Thus, by Whiteheads theorem, quasi-isomorphisms lift to homotopy equivalences. In this case the derived category of A_∞ -algebras is equivalent to the homotopy category of A_∞ -algebras.

We will conclude this section by looking at the category of algebras as a subcategory of A_∞ -algebras. The derived category may then be expressed as the homotopy category A_∞ -algebras, restricted to algebras.

2.1 Model categories

In this section we will define Quillens model category. As one may see is that in practice there are a plethora of semantically different definitions of model categories, however they are all made to be equivalent. The difference comes down to preference. In this thesis we will use the definitions as they are developed in Mark Hoveys book. We will then go on to prove the basic results known about model categories, its associated homotopy category and Quillen functors between model categories.

Before we state the definition of a model category we need some preliminary definitions. For this section, let \mathcal{C} be a category.

Definition 2.1.1 (Retract). A morphism $f : A \rightarrow B$ in \mathcal{C} is a retract of a morphism $g : c \rightarrow D$ if it fits in a commutative diagram:

$$\begin{array}{ccccc}
 & & id_A & & \\
 & \curvearrowright & & \curvearrowleft & \\
 A & \longrightarrow & C & \longrightarrow & A \\
 \downarrow f & & \downarrow g & & \downarrow f \\
 B & \longrightarrow & D & \longrightarrow & B \\
 & \curvearrowleft & & \curvearrowright & \\
 & & id_B & &
 \end{array}$$

Definition 2.1.2 (Functorial factorization). A pair of functors $\alpha, \beta : \mathcal{C}^{\rightarrow} \rightarrow \mathcal{C}^{\rightarrow}$ is called a functorial factorization if for any morphism $f = \beta(f) \circ \alpha(f)$. We will denote the morphisms in the factorization as f_{α} and f_{β} . The functorial factorization may be depicted by the following commutative diagram:

$$\begin{array}{ccc}
 A & \xrightarrow{f} & B \\
 & \searrow f_{\alpha} & \nearrow f_{\beta} \\
 & C &
 \end{array}$$

Definition 2.1.3 (Lifting properties). Suppose that the morphisms $i : A \rightarrow B$ and $p : C \rightarrow D$ fits inside a commutative square. i is said to have the left lifting property with respect to p , or p has the right lifting property with respect to i , if there is an $h : B \rightarrow C$ such that the two triangles commute.

$$\begin{array}{ccc}
 A & \longrightarrow & C \\
 \downarrow i & \nearrow h & \downarrow p \\
 B & \longrightarrow & D
 \end{array}$$

Remark 2.1.4. We will call the left lifting property for LLP and the right lifting property for RLP.

2.1.1 Model categories

Definition 2.1.5 (Model category). Let \mathcal{C} be a bicomplete category, i.e. has every small limit and colimit. \mathcal{C} admits a model structure if there are three wide subcategories each defining a class of morphisms:

- $Ac \subset Mor(\mathcal{C})$ are called weak equivalences
- $Cof \subset Mor(\mathcal{C})$ are called cofibrations
- $Fib \subset Mor(\mathcal{C})$ are called fibrations

In addition we call morphisms in $Cof \cap Ac$ for acyclic cofibrations and $Fib \cap Ac$ for acyclic fibrations. Moreover, \mathcal{C} has two functorial factorizations (α, β) and (γ, δ) . The following axioms should be satisfied:

- MC1** The class of weak equivalences satisfy the 2-out-of-3 property, i.e. if f and g are composable morphisms such that 2 out of f , g and gf are weak equivalences, then so is the third.
- MC2** The three classes Ac , Cof and Fib are retraction closed, i.e. if f is a retraction of g , and g is either a weak-equivalence, cofibration or fibration, then so is f .
- MC3** The class of cofibrations have the left lifting property with respect to acyclic fibrations, and fibrations have the right lifting property with respect to acyclic cofibrations.
- MC4** Given any morphism f , f_α is a cofibration, f_β is an acyclic fibration, f_γ is an acyclic cofibration and f_δ is a fibration.

A model category \mathcal{C} is now defined to be a category equipped with a particular model structure. Notice that a category may admit several model structures. We will postpone examples until sufficient theory have been developed. For more topological examples, we refer to Dwyer-Spalinski and Hovey.

An interesting and a not so non-trivial property of model categories is that giving all three classes Ac , Cof and Fib is redundant. Given the class of weak equivalences and either cofibrations or fibrations, the model structure is determined. Thus the classes of fibrations are determined by acyclic cofibrations and cofibrations are determined by fibrations. The next two results will show this.

Lemma 2.1.6 (The retract argument). *Let \mathcal{C} be a category. Suppose there is a factorization $f = pi$ and that f has LLP with respect to p , then f is a retract of i . Dually, if f has RLP to i , then it is a retract of p .*

Proof. We assume that $f : A \rightarrow C$ has LLP with respect to $p : B \rightarrow C$. Then we may find a lift $r : C \rightarrow B$, which realize f as a retract of i .

$$\begin{array}{ccc}
 A & \xrightarrow{i} & B \\
 \downarrow f & \nearrow r & \downarrow p \\
 C & \xlongequal{\quad} & C
 \end{array}
 \implies
 \begin{array}{ccccc}
 A & \xlongequal{\quad} & A & \xlongequal{\quad} & A \\
 \downarrow f & & \downarrow i & & \downarrow f \\
 C & \xrightarrow{r} & B & \xrightarrow{p} & C
 \end{array}$$

□

Proposition 2.1.7. *Let \mathcal{C} be a model category. A morphism f is a cofibration (acyclic cofibration) if and only if f has LLP with respect to acyclic fibrations (fibrations). Dually, f is a fibration (acyclic fibration) if and only if it has RLP with respect to acyclic cofibrations (cofibrations).*

Proof. Assume that f is a cofibration. By MC3, we know that f has LLP with respect to acyclic fibrations. Assume instead that f has LLP with respect to every acyclic fibration. By MC4 we factor $f = f_\alpha \circ f_\beta$, where f_α is a cofibration and f_β is an acyclic fibration. Since we assume f to have LLP with respect to f_β , by lemma 2.1.6 we know that f is a retract of f_α . Thus by MC2, we know that f is a cofibration. □

Corollary 2.1.7.1. *Let \mathcal{C} be a model category. Cofibrations are stable under pushouts, i.e. if f is a cofibration, then f' is a cofibration.*

$$\begin{array}{ccc}
 A & \longrightarrow & C \\
 \downarrow f & \lrcorner & \downarrow f' \\
 B & \longrightarrow & D
 \end{array}$$

Dually, fibrations are stable under pullbacks.

Proof. Maybe, if I am in the mood 🧑🏻👉👑 □

Since we assume that every model category \mathcal{C} is bicomplete, we know that it has both an initial and a terminal object. We let \emptyset denote the initial object and $*$ denote the terminal object.

Definition 2.1.8 (Cofibrant, fibrant and bifibrant objects). Let \mathcal{C} be a model category. An object X is called cofibrant if the unique morphism $\emptyset \rightarrow X$ is a cofibration. Dually, X is called fibrant if the unique morphism $X \rightarrow *$ is fibrant. If X is both cofibrant and fibrant, we call it bifibrant.

There is no reason for every object to be either cofibrant or fibrant. However, we may see that every object is weakly equivalent to an object which is either fibrant or cofibrant. We make the following remarks.

Remark 2.1.9. Let X be an object of a model category \mathcal{C} . The morphism $i : \emptyset \rightarrow X$ has a functorial factorization $i = i_\beta \circ i_\alpha$, where $i_\alpha : \emptyset \rightarrow QX$ is a cofibration and $i_\beta : QX \rightarrow X$ is an acyclic fibration. By definition QX is cofibrant and weakly equivalent to X .

$Q : \mathcal{C} \rightarrow \mathcal{C}$ defines a functor called the cofibrant replacement. To see this we first look at the slice category \emptyset/\mathcal{C} . The objects are morphisms $f : \emptyset \rightarrow X$ for any object X in \mathcal{C} , while morphisms are commutative triangles. We first observe that $\emptyset/\mathcal{C} \subset \mathcal{C}^{\rightarrow}$ is a subcategory of the arrow category. Thus (α, β) may be interpreted as functors on the slice category to the arrow category. Moreover, since every arrow $f : \emptyset \rightarrow X$ is unique, we observe that this category is equivalent to \mathcal{C} . Thus (α, β) may be interpreted as functors on \mathcal{C} into arrows. We define Q as the composition $Q = \text{tar} \circ \alpha$.

Dually, we get a fibrant replacement R by dualizing the above argument.

Our first step towards the generalized Whiteheads theorem is Ken-Brown's lemma.

Lemma 2.1.10 (Ken Brown's lemma). *Let \mathcal{C} be a model category and \mathcal{D} be a category with weak equivalences satisfying the 2-out-of-3 property. If $F : \mathcal{C} \rightarrow \mathcal{D}$ is a functor sending acyclic cofibrations between cofibrant objects to weak equivalences, then F takes all weak equivalences between cofibrant objects to weak equivalences. Dually, if F takes all acyclic fibrations between fibrant objects to weak equivalences, then F takes all weak equivalences between fibrant objects to weak equivalences.*

Proof. Suppose that A and B are cofibrant objects and that $f : A \rightarrow B$ is a weak equivalence. Using the universal property of the coproduct we define the map $(f, id_B) = p : A \amalg B \rightarrow B$. p has a functorial factorization into a cofibration and acyclic fibration, $p = p_\beta \circ p_\alpha$. We recollect the maps in the following pushout diagram:

$$\begin{array}{ccc}
 \emptyset & \longrightarrow & B \\
 \downarrow & \lrcorner & \downarrow i_2 \\
 A & \xrightarrow{i_1} & A \amalg B \\
 & \searrow f & \downarrow p_\alpha \\
 & & C \\
 & \nearrow p_\beta & \downarrow p_\beta \\
 & & D
 \end{array}$$

(Note: The diagram also includes a curved arrow from \emptyset to D labeled id_B and a curved arrow from A to D labeled f .)

By lemma 2.1.7.1 both i_1 and i_2 are cofibrations. Since f , id_B and p_β are weak equivalences, so are $p_\alpha \circ i_1$ and $p_\alpha \circ i_2$ by MC2. Moreover, they are acyclic cofibrations.

Assume that $F : \mathcal{C} \rightarrow \mathcal{D}$ is a functor as described above. Then by assumption, $F(p_\alpha \circ i_1)$ and $F(p_\alpha \circ i_2)$ are weak equivalences. Since a functor sends identity to identity, we also know that $F(id_B)$ is a weak equivalence. Thus by the 2-out-of-3 property $F(p_\beta)$ is a weak equivalence, as $F(p_\beta) \circ F(p_\alpha \circ i_2) = id_{F(B)}$. Again, by 2-out-of-3 property $F(f)$ is a weak equivalence, as $F(f) = F(p_\beta) \circ F(p_\alpha \circ i_1)$. \square
